Darwin College, University of Cambridge, CB3 9EU, United Kingdom

Education

University of Cambridge 2022 – 2027 (expected)
PhD in Economics
Advisors: Eric French, Weilong Zhang

University of Cambridge 2020 – 2021
MPhil in Economic Research (Distinction)

University of Edinburgh 2016 – 2020
MA in Economics (First Class Honours, Ranked 1st in Cohort)

University of Pennsylvania (Exchange) 2018 – 2019
GPA: 3.96/4.0, Dean's List

Research Interests

Health Economics, Labor Economics, Public Economics, Behavioral Genetics, Applied Microeconomics.

Job Market Paper

The "Depression Trap": Genetic Risk, Labor Supply, and the Case for Precision Psychiatry
Joint with Qianyu Yang

Abstract. Why is depression linked to persistent non-employment, and how can treatment be better targeted to improve mental health and employment outcomes? Using longitudinal UK panel data, we provide evidence for the "depression trap": a self-reinforcing cycle of poor mental health and non-employment, using event studies of depression recurrences and redundancies (layoffs). We link our panel to molecular genetic data and show that individuals with high genetic risk for depression are significantly more likely to enter the depression trap and less likely to leave it. We evaluate allocating treatment by genetic risk using a structural life-cycle model of health, labor supply and treatment in which employment decisions reinforce mental-health shocks. We find that targeting therapy towards individuals with high genetic risk for depression improves welfare and raises the clinical efficacy of treatment by 31%. Furthermore, we find that the information provided by genetic risk generates a net fiscal surplus sufficient to finance the cost of universal genotyping, by increasing employment through improved treatment allocation.

Working Papers

The Economic Cost of Depression: Triangulation Using Panel and Mendelian Randomization Analyses
Joint with Robert Campbell and Benjamin Woolf

Abstract. Depression, poor educational attainment, poor health, and unemployment form a correlated web that reduces human flourishing, but the causal links between them are unclear. We estimate the causal effect of depressive symptoms on educational and labour market outcomes by triangulating four research designs across economic, clinical, and genomic data. In UK longitudinal data (305,686 person-wave observations), a one standard-deviation (s.d.) rise in depressive symptoms lowers income in the following wave by 0.036 s.d. and employment by 0.044 s.d.; instrumenting symptoms with bereavement gives larger but less precise short-run estimates. Two genetic designs capture lifetime liability: two-sample Mendelian randomization on summary statistics from up to 2.1 million individuals, and a polygenic index instrument in the genotyped UKHLS subsample. In these designs, genetic liability to depression lowers income by 0.24–0.49 s.d., educational attainment by 0.14–0.46 s.d., and occupational status by 0.36–0.65 s.d. The education and occupation penalties fall almost entirely on women, while most of the income penalty for both sexes runs through employment rather than pay. The economic cost of depression accumulates over the life course, so treatment before labour-market entry may yield the largest economic returns.

Not All Made Equal? Genetics, Ageing and Wellbeing: Evidence from the UK
Joint with Alan Piper (draft available upon request)

Abstract. Life satisfaction is U-shaped over the life cycle, and roughly 40% of the variation in wellbeing is heritable. We ask how genetic predispositions for wellbeing interact with ageing. Matching a wellbeing polygenic index (PGI) to panel data from the British Household Panel Survey and the UK Household Longitudinal Study, we establish three results. First, the PGI predicts substantial and statistically significant differences in life satisfaction at *every* point in the life cycle. Second, the U-shaped age profile of wellbeing holds *within* both high- and low-PGI groups. Third, individuals with a lower PGI face a *more pronounced* U-shape, so the genetic wellbeing gap is widest in middle age and narrower at the tails. The first two findings are robust to a within-family design that controls for parental PGIs, while the third fails to replicate in the within-family sample. A mediation analysis shows that declining physical health accounts for roughly one-third of the age variation in the gap.

Works in Progress

The Genetic Child Penalty: Evidence from the UK and Norway
Joint with Emil Sørensen, Stephanie von Hinke, and Eivind Ystrøm

Abstract. Does the child penalty reinforce genetic inequality? Using Norwegian administrative data linked to molecular genetic information, we estimate gene–environment ($G \times E$) event studies around first birth. Women below the median polygenic index for educational attainment experience an employment penalty 1.5 percentage points larger initially, widening to 4 percentage points after ten years. The gap persists controlling for education, implying mechanisms beyond schooling. UK household panel data corroborate the pattern. Policies reducing the child penalty generate a double dividend: improving gender equality *and* attenuating the economic consequences of the genetic lottery.

Genetic and Economic Interaction in Health Formation: The Case of Obesity
Joint with Pietro Biroli and Qianyu Yang

We develop a structural model of health and human capital formation in which genetic endowments shape both the utility cost of health investments and the technology of health production, and hence the incentives to invest in healthy habits. Taking body mass index as the measure of health and physical activity and food intake as the investments, we study how these choices interact with variants in *FTO* and other loci associated with BMI in genome-wide association studies, using cohort data on British adolescents and US adults.
